HOUSING: BOX AND PANEL

William H. Soupcoff

Submitted to the Department of Architecture on May 9, 1975, in partial fulfillment of the requirements for the degree of Master of Architecture.

The purpose of this thesis has been to do an in depth study of Housing using a system of prefabricated steel boxes and infill panels. The boxes are wholly fabricated in a factory containing all service components, stair, kitchen, bathrooms, etc. and then transported to site for erection. The infill panels, between boxes, are also partially fabricated in the factory and shipped to the site for erection. The assembly of the steel components in the factory has been designed to easily adapt to the existing Mobile Home production techniques. Using standard steel components has made it possible to address a nationwide market. The system is capable of going to at least 9 stories in height without any major changes to box and panel design.

The system does have specific limitations in planning due to the structural interdependency of box and panel. Another limiting factor is that all the mechanical elements have to be contained within the box. Even with these limitations, I feel that there is enough flexibility to design excellent living environments for people.

# **INTRODUCTION**

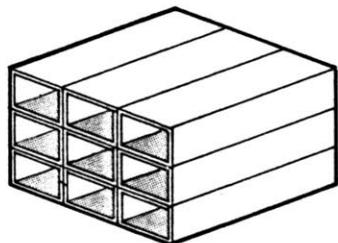

## **GOALS:**

To develop a housing system capable of:

- 1) Using the existing production techniques of the Mobile Home Industry.
- 2) Combining on-site and factory production.
- 3) Appealing to a nationwide market.
- 4) Use for mobile homes, midrise, and highrise.
- 5) Use for houses and apartments up to 4 bedrooms in size.
- 6) Integrating with and respecting traditional American architectural character.

## SYSTEM COMPARISON:

### **Boxes Stacked**

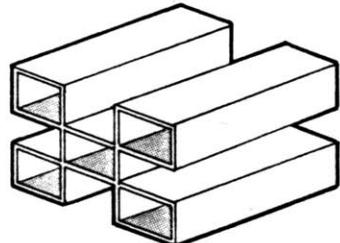

#### Major Advantages:

- 1) Complete factory production.
- 2) Minimum of site labor.

#### Major Disadvantages:

- 1) Redundance of walls, ceiling, and floor.
- 2) Transplanting large amounts of space.
- 3) No variation in dimensions of room width.

### **Boxes Staggered**

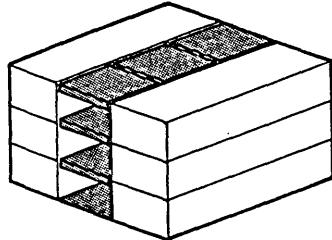

#### Major Advantages:

- 1) Minimizes redundancy of walls, floors, ceilings.
- 2) Transport one-half as many boxes.

#### Major Disadvantages:

- 1) Plumbing does not stack.
- 2) Planning difficulty due to total structural dependency of one box to another.

## **Box & Panel**

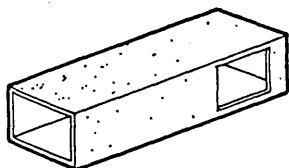

### Major Advantages:

- 1) Plumbing stacks vertically.
- 2) Minimal shipment of air.
- 3) Capable of large spans between boxes.

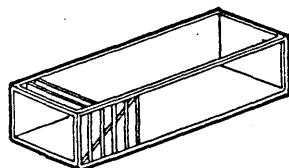

### Major Disadvantages:

- 1) Planning is limited because of interdependency of panel upon box.
- 2) Field labor needed to finish interior of panel space.

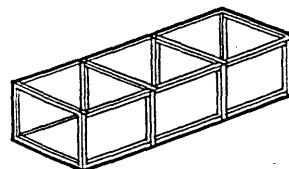

## MATERIAL COMPARISON:

Concrete does not lend itself to the mass production technique of the Mobile Home Industry. Most Mobile Home factories are set to operate on a 20 min. (app.) rotation cycle time, because of concrete's long curing time. This would be prohibitive even with quick curing concrete. Also, concrete boxes address themselves to more specialized market, highrise construction, and therefore limit their application to a nationwide market.

Wood is the most common structural material in use today for fabrication of mobile home units, but it has obvious limitations in highrise construction both structurally and in meeting fire limitations.

Steel offers a nationwide market because of accessibility of standard steel sections. Steel also provides the structural capability of highrise construction. Although steel is restricted by fire limitations, it is possible to build to 9 stories in height with reasonably low fire rating requirements. (9 story steel construction = use group L-2 - 3/4 hr. fire rating of all structural members + 1 1/2 hr. fire rating on ground floor) Steel offers the designer a structural skeleton with max. planning flexibility.

## FIRE CODE LIMITATIONS:

(Boca Code)

Use Group: L-2 (multi-family residential)

Construction Classification: (noncombustable construction) Type 2

### FIRE RESISTANCE RATINGS FOR TYPE 2 CONSTRUCTION

Structural Elements	Hours of Fire Protection		
	2A	2B	2C
Fire Walls	2 hr.	2 hr.	2 hr.
Fire Divisions	1 1/2	1 1/2	1 1/2
Fire Enclosure of Exitways, Lifts, Exitway Hallways, and Stairways	2	2	2
Shafts other than Stairways	2	2	2
Exitway Access Hallways and Vertical Separation of Tenant Spaces	3/4	3/4	0
Columns, Girders, Trusses (other than roof trusses) and Framing	1 1/2	3/4	0
Structural Members supporting Walls	1 1/2	1 1/2	1 1/2
Floor Construction including beams	1 1/2	3/4	0

### HEIGHT LIMITATIONS AND FLOOR AREA LIMITATIONS

L-2 (multi-family residential)	9st.-100'	4st.-50'	3st.-40'
*Max. Floor Area	22,800	15,000	9,600

\*Note:

There is a sq. ft. area/floor reduction as building goes above first floor. The chart on the following page indicates these reductions.

AREA LIMITATION ADJUSTMENTS

No. of Stories	Reduct.	Sq. Ft.	Reduct.	Sq. Ft.
	Factor		*2B	
1	none	22,800	none	15,000
2	none	22,800	none	15,000
3	5%	21,660	20%	12,000
4	10%	20,520	20%	12,000
5	15%	19,400	30%	10,500
6	20%	18,240	40%	9,000
7	25%	17,100	50%	7,500
8	30%	15,960	60%	6,000
9	35%	14,820	70%	4,500

\*PROTECTED NONCOMBUSTABLE CONSTRUCTION: (Boca Code 905.62)

When of 3/4 hr. protected noncombustable (type 2-B) construction, multi-family dwellings (use group L-2) may be increased to 9 stories or 100' in height when separated not less than 50' from any other building on the lot and from interior lot lines, the exitways are segregated in a fire area enclosed in a continuous fire wall of 2 hr. fire resistance and the first floor is not less than 1 1/2 hr. fire resistive construction.

## Note:

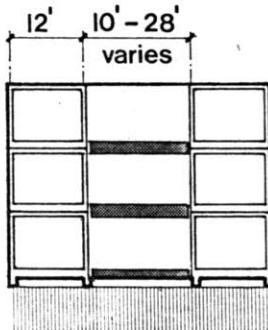

Two buildings, while being separated by 50', can be linked by a corridor or passage that is properly treated with 2 fire resistant construction.

## Notes:

1. FIRE RETARDANT PLYWOOD is considered noncombustable and can be used in Type 2 construction.
2. Floor joists and/or ceiling joists need only be fire proofed from bottom and not from top.
3. FIRE WALLS must be continuous and extend from foundation to 2'-8" above roof line.

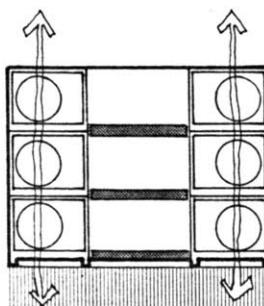

## DECISION:

Upon completion of comparative analysis of preceding building systems and structural materials, I have chosen to study a system of steel boxes and infill panels.

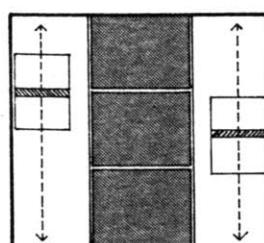

Box is a constant 12' width measured from center line of steel columns.

Panel is a variable which can change dimension from 10' - 28' in width.

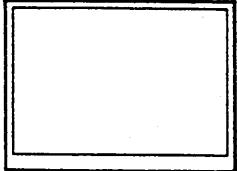

All wet core elements plumbing walls are prefabricated in factory and installed into box. Therefore, only the vertical connection from one plumbing wall to next is necessary in field. (assuming plumbing stacks)

It is possible to run plumbing horizontally in ceiling space but this is discouraged because of possible intervention with mechanical heat ducts or pipes.

Plumbing wet wall may be located freely in box according to design.

## CONSTANT

The Box, which will be considered the CONSTANT element, is wholly fabricated in the factory. Because factory production is almost 1/2 the cost of field labor, it is desirable to do as much work as possible in the factory. For this reason all services (bathrooms, kitchens, etc.) will be factory installed in box in order to minimize field labor.

### Components

- bathrooms
- kitchens
- stair
- mechanical room
  - furnace
  - washer
- dryer
- hot water heater

## VARIABLE

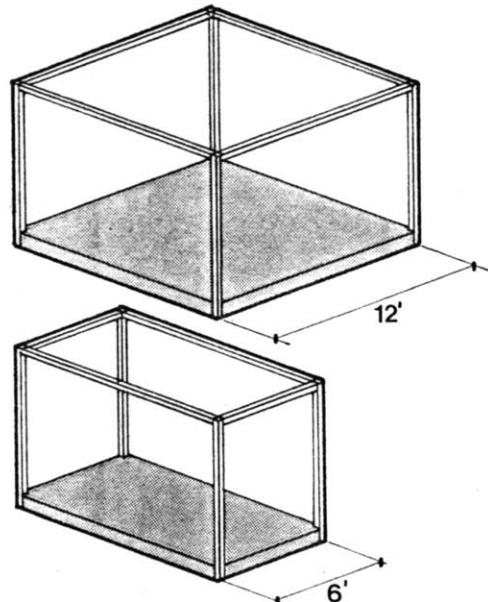

The INFILL PANEL, which will be considered the VARIABLE element, is partially fabricated in the factory. Because of the need to make structural and mechanical connections, the ceiling of the floor panel will be erected after it has been placed and bolted to adjoining boxes. All interior partitions will also be partially prefabricated in factory, shipped to site, erected, and finished by field labor.

### Components

- non-service areas
  - living room
  - family rooms
  - bedrooms
- storage
- decks
- 2-story spaces
- pitched roofs

# **STRUCTURE**

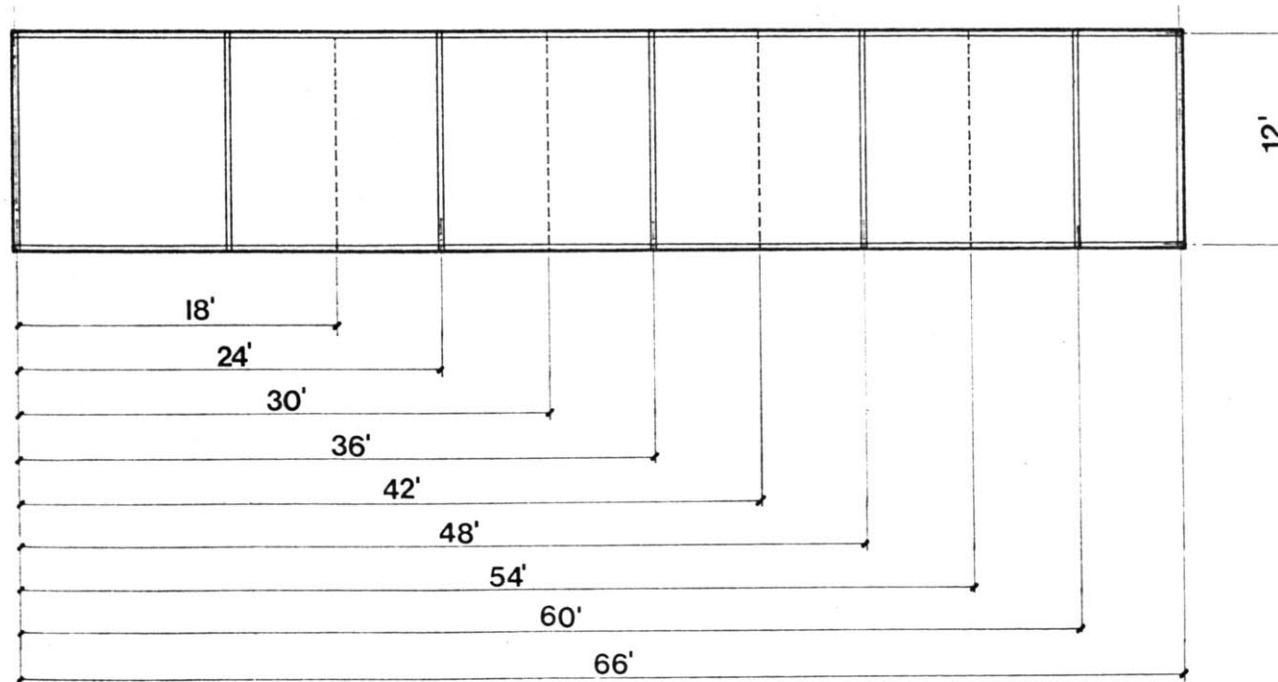

## BOX:

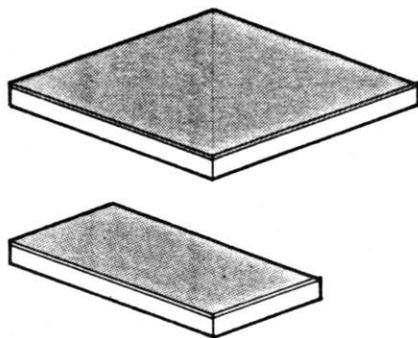

Box Structure is based on a 12' and 6' structural bay, measured to centerline of column.  
By combining these 2 bay sizes, various size boxes can be fabricated, ranging from 18' to 66' in length.

Boxes 67 feet in length are max. allowable by highway transportation limitations.

Most Common box lengths:

Townhouses 24' to 42'  
Lowrise Apartments 24' to 42'  
Highrise Apartments  
single loaded 24' to 30'  
double loaded 42' to 60'

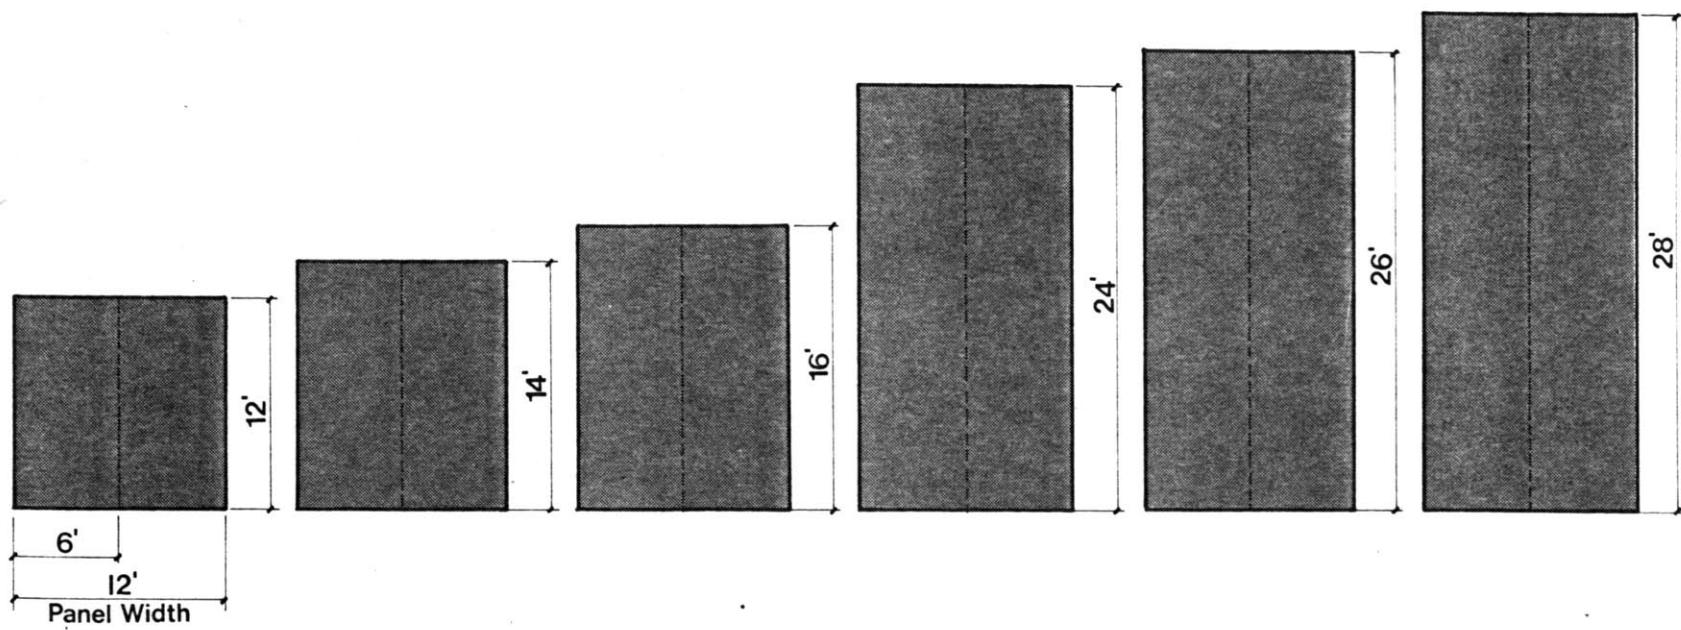

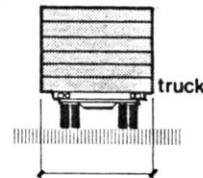

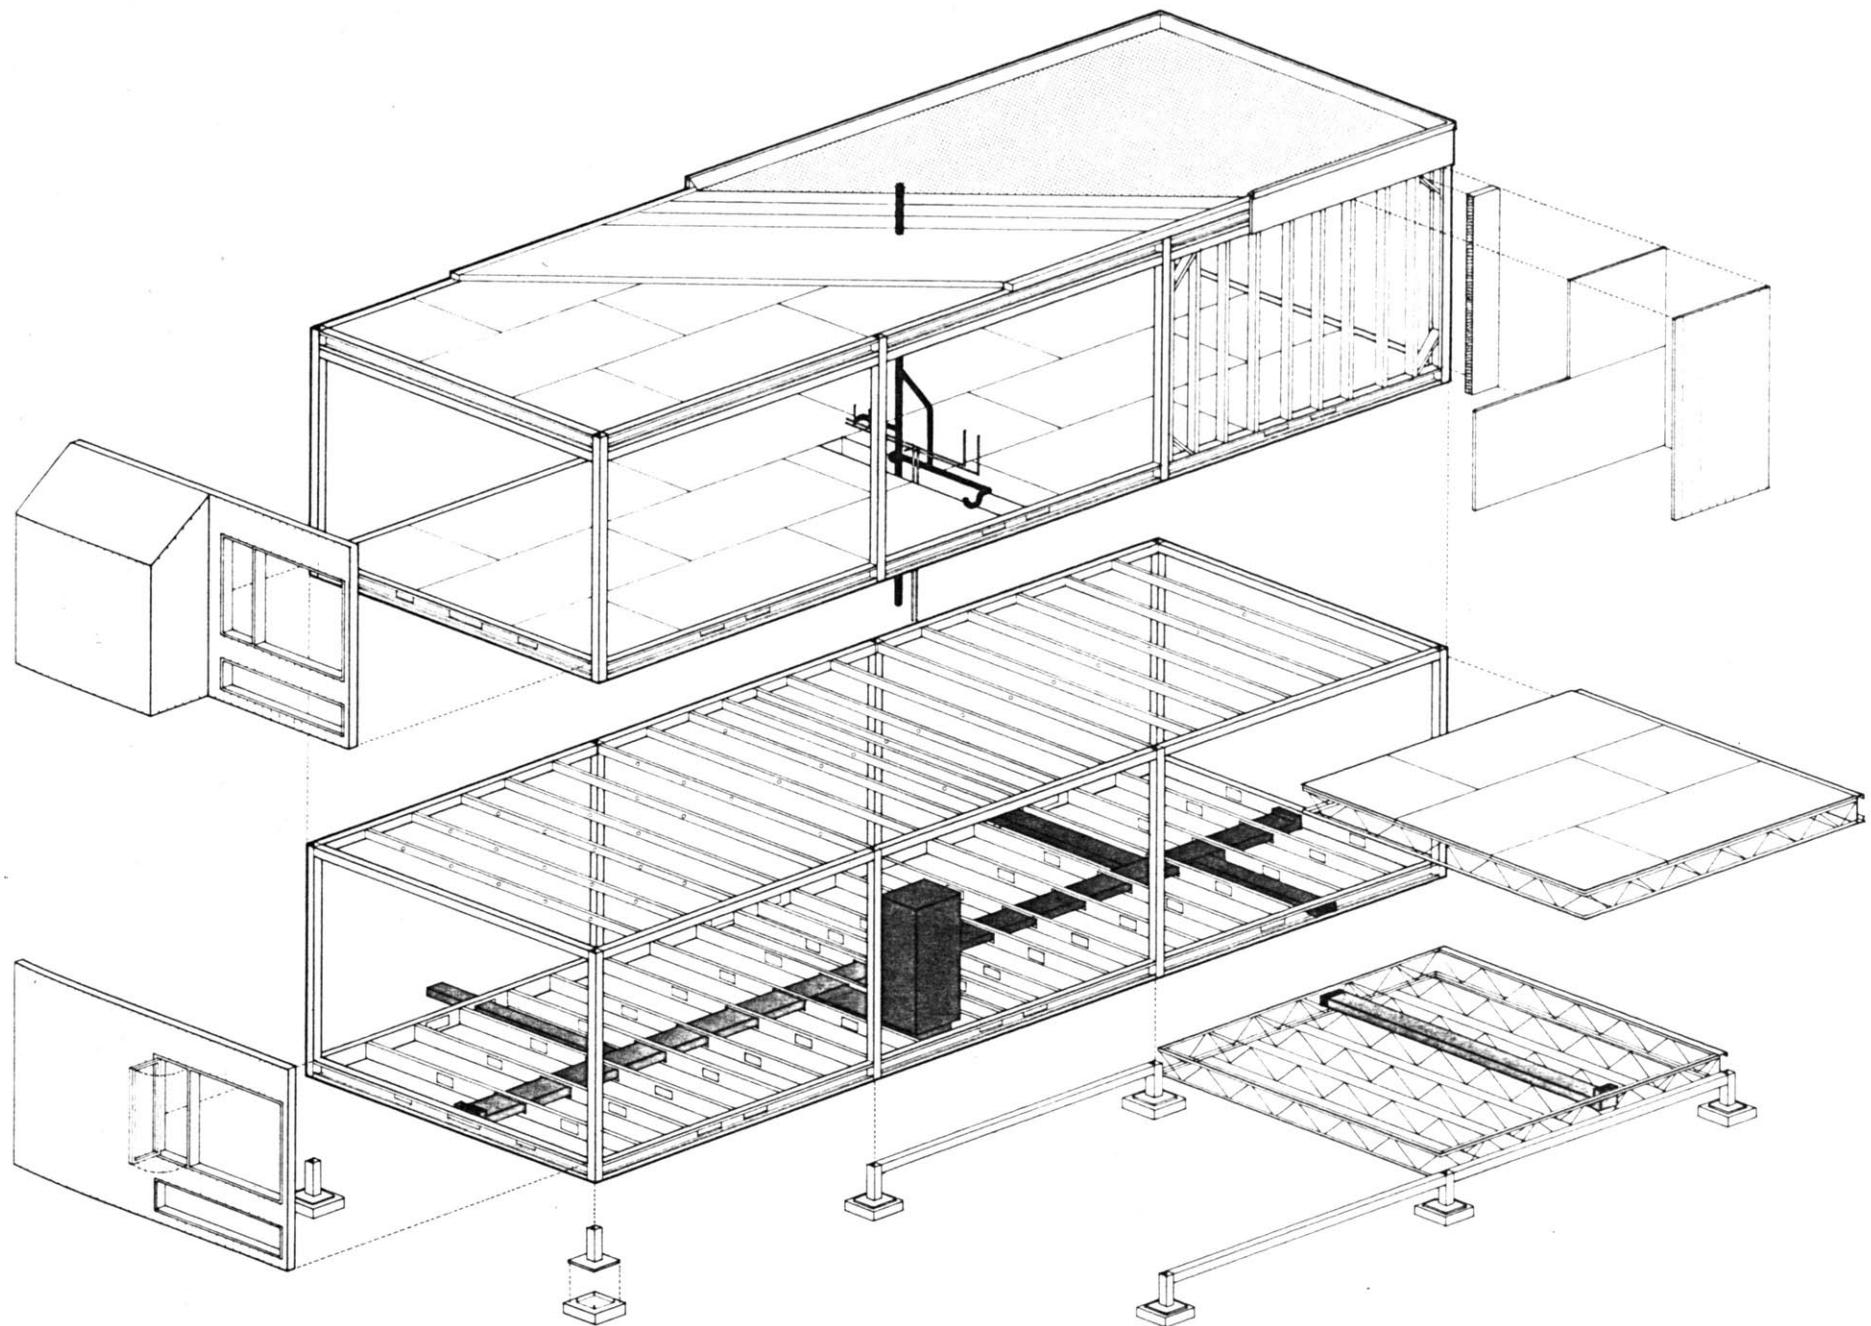

### INFILL PANEL:

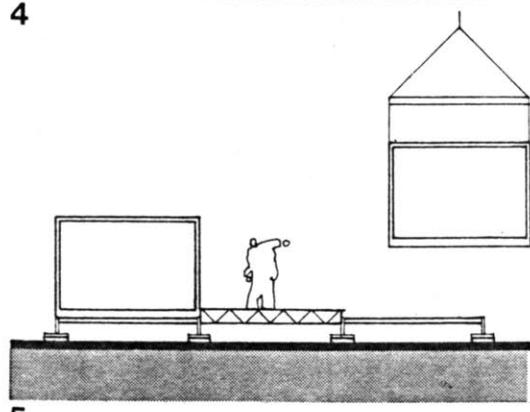

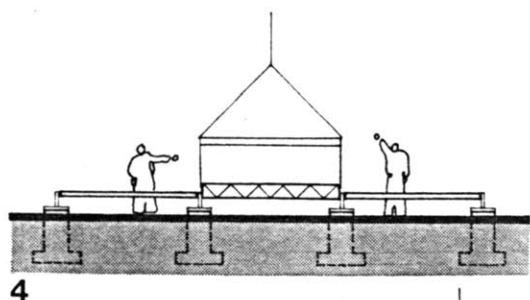

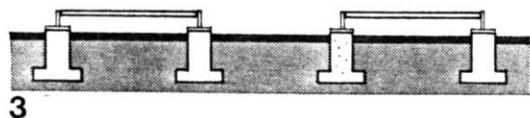

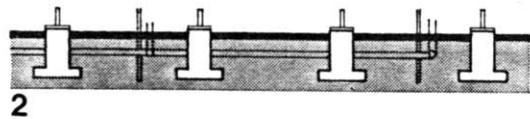

Panel Structure is based on a constant 12' and 6' width. Panel lengths variable and may be 12', 14', 16', 24', 26', and 28'.

Panels stacked horizontally during transportation.

**EXPLODED AXONOMETRIC**

#### SITE:

1

2

3

4

5

#### SITE PREPARATION:

1. Install all ground services (ele., plumbing, sewage, etc.)
2. Build forms and pour foundation levers.
3. Set and bolt foundation column cap.

#### PREPARE FOUNDATIONS:

1. Set and bolt closure beams.
2. Erect masonry block wall between piers.
3. Place and bolt infill bearing beams.

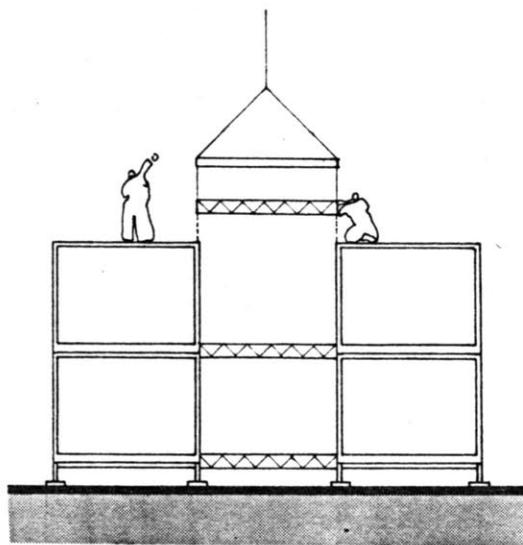

#### PANEL ERECTION:

1. Place floor infill panel.
2. Bolt floor panel to beam.

#### BOX ERECTION:

1. Connect box to foundation cap.
2. Bolt box to floor panel.
3. Connect air ducts between box and floor panel.
4. Connect electrical lines.
5. Connect plumbing to ground services.

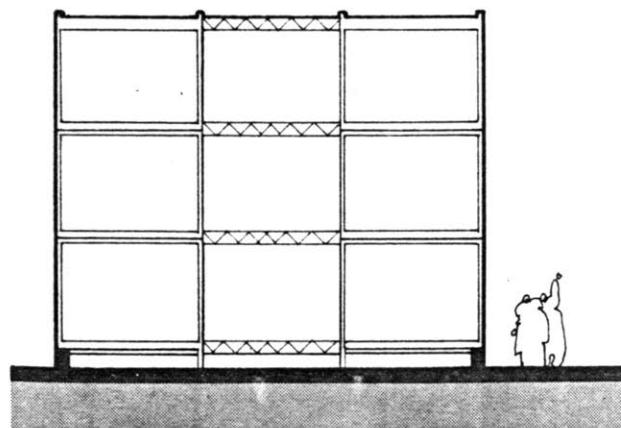

## SITE ERECTION

6

#### SECOND FLOOR ERECTION:

1. Place and connect floor panel to boxes.
2. Connect mechanical ducts.
3. Connect plumbing wet wall between first floor box and second floor box.
4. Install interior wall partitions in infill area between boxes. (first floor)
5. Install exterior wall infill on first floor.

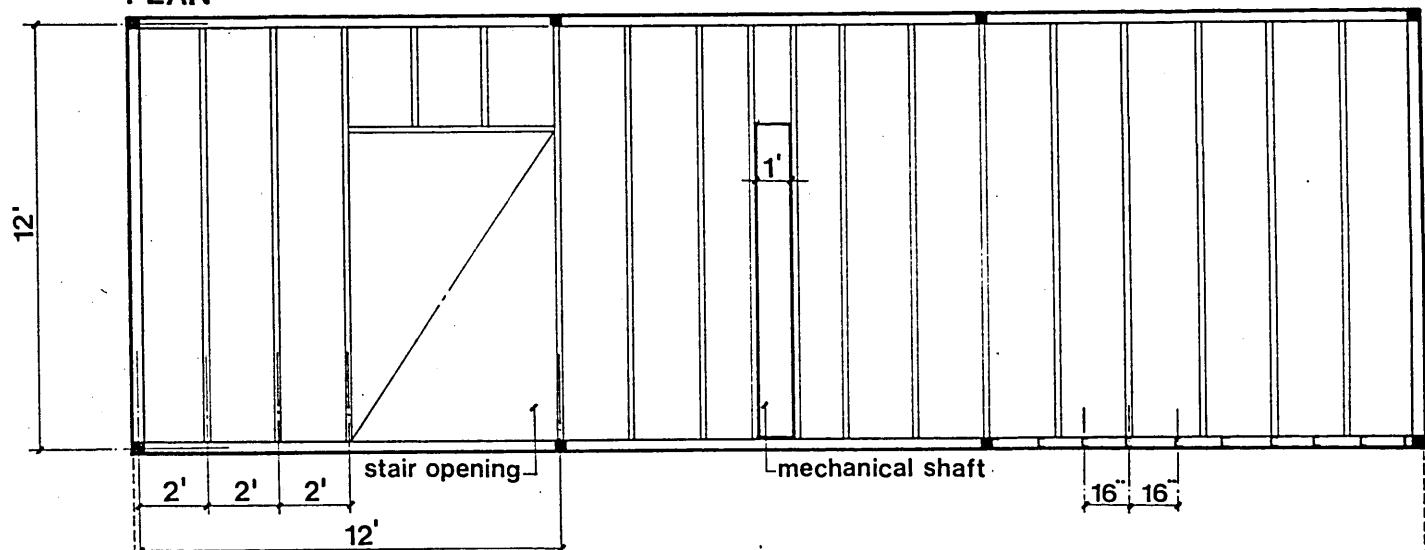

7

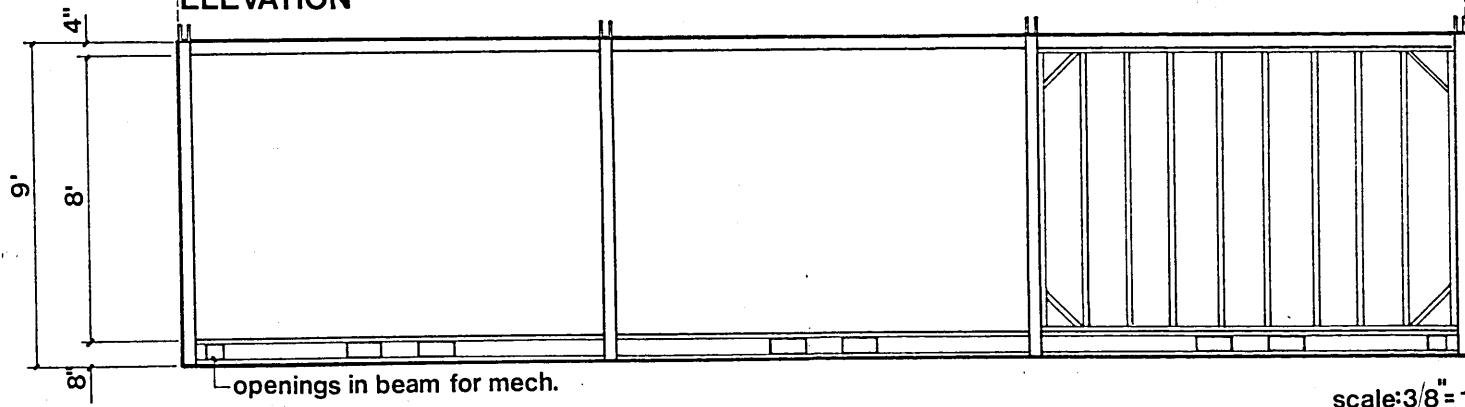

#### FINSH WORK:

1. All interior finishes in the infill zone to be completed.
2. Exterior facia strip placed at floor joints.
3. Roof flashing connections.
4. Site work.
  - a. landscaping
  - b. parking
  - c. lighting
  - d. etc.

## MECHANICAL STUDY

The following study is primarily made for individual or combined lowrise housing units, but the principles are valid for analyzing the heating needs for most small building structures. This study is directed at quickly analyzing and calculating where and how heat is lost from a house. Upon determining where and how heat is being lost, "Rule of Thumb" estimates can be used for determining amount of BTU/Hr. heat loss. This information can be used in comparing different types of fuel, to size and pick individual furnace and boiler types, or to be combined with other house loads to determine loads for a central heating system.

### DEFINITIONS:

BTU (British Thermal Unit) is the heat or energy needed to raise one pound of water 1° Fah.

U-Coefficient is the number of BTU/Hr. that pass through one square foot of wall, floor, roof, etc., when temperature difference between inside and outside is 1° Fah.

### COSTS:

If costs were not an important factor in determining which fuel to use for heating, most builders and users would pick Electricity, Gas, Oil, and Coal, in that order. Electricity has the advantages of instantaneous response, individual thermostatic control, and metering, no combustable parts, being clean, and being quiet. The other fuel sources need combustable parts; also Oil and Coal are not only dirty but need large storage areas.

Because cost is many times the decision maker in determining the type of fuel to be used, it is important to know the relative efficiencies of the four major fuels and their costs/unit.

FUEL	HEAT/UNIT	EFFICIENCY
Electricity	3.41 BTU/watt	95 - 100%
Gas	1,052 BTU/cub. ft.	70 - 80%
Oil	141,000 BTU/gal.	70 - 80%
Coal	14,600 BTU/lb.	65 - 75%

## COSTS: (Continued)

In order to make a rough cost comparison of the various fuel types, one only needs to know the amount of energy (BTU/Hr.) to heat a building and the cost of each fuel source in a given locale.

### Formula:

$$\frac{\text{BTU/Hr. (needed heat house)}}{\text{BTU's (per unit) x efficiency}} = \text{UNITS/Hr.} \times \text{COST/UNIT} = \$/\text{Hr.}$$

### Example:

given: 1 gallon of Oil = 141,000 BTU

given: efficiency of fuel = 75%

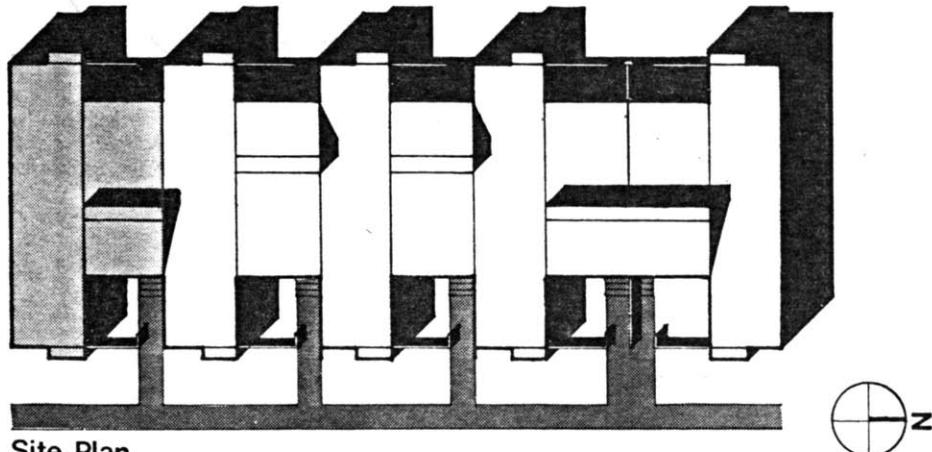

assume: 40¢ per gallon

assume: 100,000 BTU/Hr. needed to heat house

$$\frac{100,000 \text{ BTU/Hr.}}{141,000 \text{ BTU/gal} \times 75\% \text{ efficiency}} = .95 \text{ gal/Hr.} \times 40\text{¢ gal.} = 38\text{¢/Hr.}$$

### Note:

By computing for each fuel, one can quickly compare fuel costs.

Site Plan

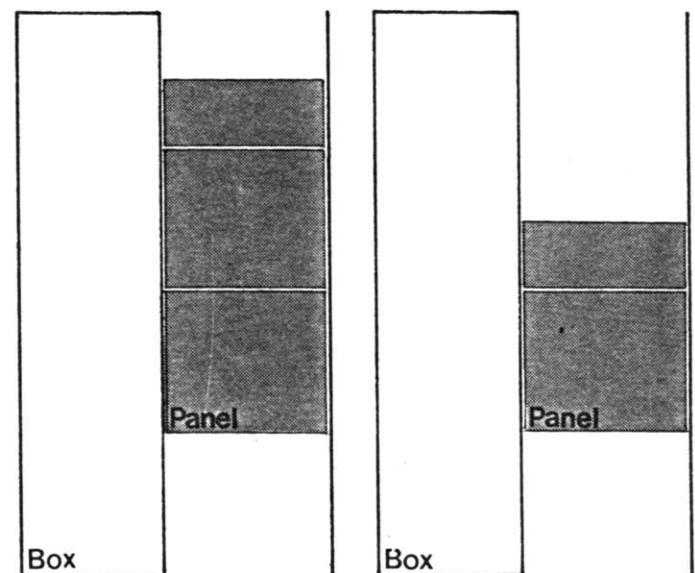

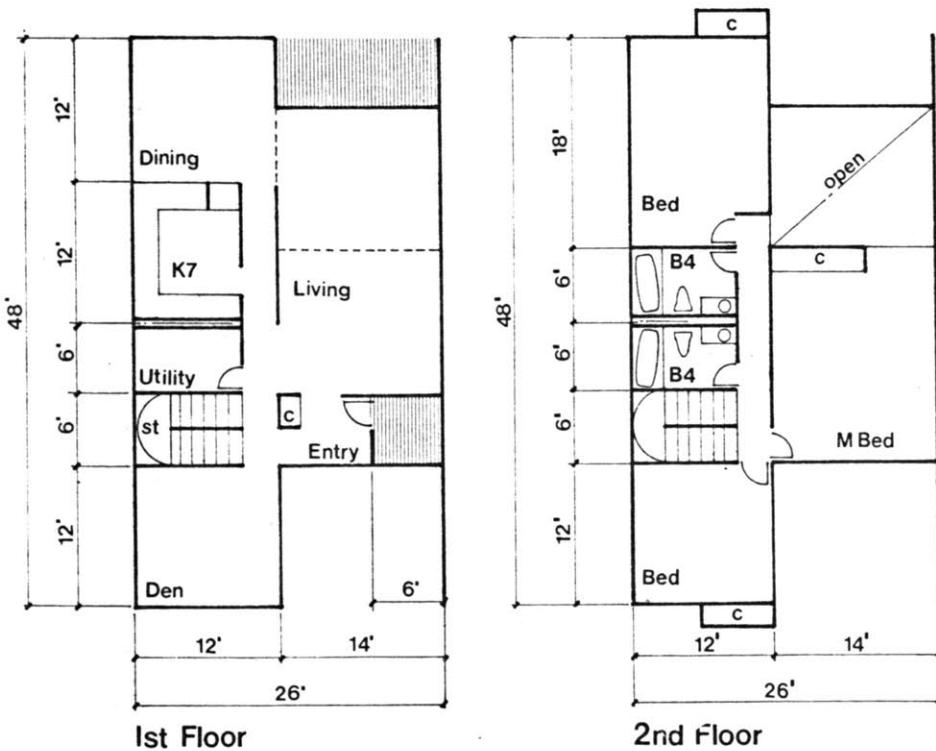

## DESIGN CRITERIA:

### HEAT LOSS EXAMPLE

Objective: Determine BFUH Loss thru Building

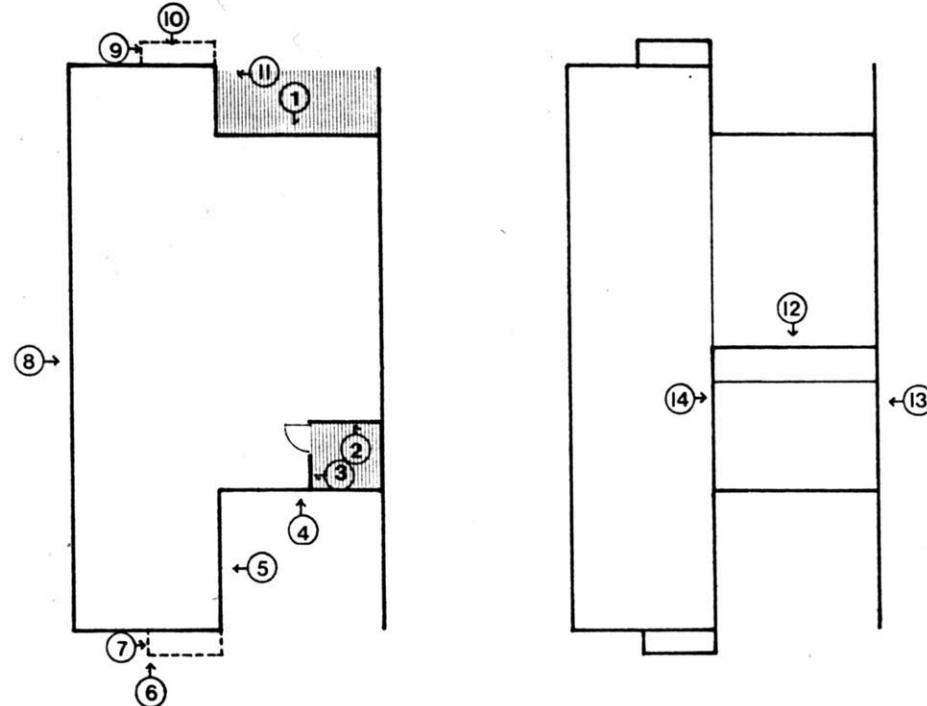

#### Assumptions:

1. Area - New England
2. Calculate for worst condition - nighttime
3. Design temperatures: 70° activity areas  
66° sleeping areas  
64° storage areas
4. Insulating glass (1/4" air space)
5. Wood door (1 1/2" solid)
